EvaLuation Using Cardiac Insertable Devices And TelephonE in Hypertrophic Cardiomyopathy (ELUCIDATE HCM)—rationale and design: a prospective observational study on incidence of arrhythmias in Sweden

Peter Magnusson,1,2 Stellan Mörner3

ABSTRACT

Introduction Hypertrophic cardiomyopathy (HCM) is a heterogeneous disease associated with sudden cardiac death (SCD) mainly due to ventricular tachycardia (VT) or fibrillation even though life-threatening bradycardia occurs. Risk stratification takes several variables into consideration including non-sustained VT (NSVT). An implantable cardioverter defibrillator effectively prevents SCD. Atrial fibrillation (AF) is common among patients with HCM and warrants anticoagulation even without conventional risk factors according to European guidelines. Routinely, the evaluation of arrhythmias using a 48-hour ambulatory external monitor takes place every 6–24 months if patients do not report palpitations. The remaining time the potential burden arrhythmia is unknown. Therefore, the aim of the present study is to assess NSVT and AF incidence during 18 months by an inserable cardiac monitor (ICM).

Methods Adult patients, aged 18–65 years, with a validated diagnosis of HCM are eligible for the study. The study sample is planned to include 30 patients. A Confirm Rx is implanted at the level of the fourth rib on the left side subcutaneously after local anaesthesia. The application for monitoring is installed in the patients' smartphone and symptoms registered by the patient activation and VT detection programmed as 160 bpm during ≥8 intervals. An AF episode is recorded based on ≥2min duration. Bradycardia is recorded at ≤40 bpm or pause ≥3.0 s. The patients are followed during 18 months before explant.

Ethics and dissemination The study was approved by The Regional Ethical Committee in Umeå (protocol number 2017/13–31). The study protocol, including variables and prespecified research questions, the study was registered at Clinical Trial Registration NCT03259113. Each patient is informed about the study in both oral and written form by a physician and included after written consent.

INTRODUCTION

The hypertrophic cardiomyopathy (HCM) phenotype in adults requires at least 15 mm thickness of the myocardial wall deemed unexplained by other myocardial diseases and abnormal loading conditions due to hypertension or aortic stenosis.1 The point prevalence is approximately 1:500 in the general population but more than double if genotypes are also included.2–4 Patients present with unspecific symptoms such as dyspnoea, chest discomfort, palpitations and dizziness. Echocardiogram is the cornerstone in diagnosing HCM but integrated medical information and awareness of differential diagnoses are important to avoid misclassification.5–7 The severity and pattern of hypertrophy and disease progression varies considerably.5 Life expectancy in general HCM cohorts seems to be acceptable but end-stage heart failure, cardiac embolisation

Strengths and limitations of this study

► An inserable cardiac monitor (ICM) allows for monitoring of atrial fibrillation, significant bradycardia and non-sustained ventricular tachycardia during 18 months.
► The study will evaluate true incidence of arrhythmia including symptom registration using a smartphone.
► Non-sustained ventricular tachycardia is a marker of sudden cardiac death, but the decision to implant a defibrillator should be carefully evaluated using guidelines as an ICM is currently not an indication as a diagnostic tool in this regard.
► The costly and invasive ICM may need to be studied in larger hypertrophic cardiomyopathy cohorts to allow for subgroup analyses and to generalise findings.

stroke and devastating arrhythmias remain a challenge to improve prognosis.8–12

Sudden cardiac death (SCD) can be prevented by an implantable cardioverter defibrillator (ICD). In a recent review of patients with HCM and ICDs, 4.8% experienced appropriate therapy annually due to ventricular tachycardia (VT) or fibrillation and antitachycardia pacing or cardioversion rarely fails in terminating the arrhythmia.13 The decision to implant an ICD as primary prevention of SCD is based on evaluation of risk markers according to guidelines.14 15 In both 2011 and 2014 guidelines, non-sustained VT (NSVT) is part of risk stratification based on evidence from several studies.16–19 It is more common at an older age and correlates with increased left ventricular wall thickness.16 20 NSVT may be revealed during an ambulatory ECG in the ward or during exercise test. HCM guidelines advocate follow-up including 48 hours ambulatory ECG whenever onset of palpitations or otherwise every 12–24 months but 6–12 months if the patient is in sinus rhythm and has enlarged left atrial diameter which predisposes for atrial fibrillation (AF) and SCD.15 This implies that during the remaining time, the presence of NSVT/AF is unknown.

In HCM, AF is known to worsen symptoms due to vulnerability to increased heart rate and lack of atrial filling. Furthermore, AF associated with ischemic stroke or systemic embolisation is a major cause of death in HCM, which warrants attention to detection methods with increased sensitivity.13 In fact, according to current HCM guidelines, a history of AF, even without any CHA2DS2-VASc risk factor is an indication of anticoagulation.15

The insertable cardiac monitor (ICM) Confirm Rx (Abbott/St Jude Medical, St Paul, Minnesotta, USA) provides long-term monitoring of atrial and ventricular arrhythmias in addition to bradycardia.21 This device could potentially reveal the true incidence of arrhythmia in patients with HCM which is the rationale of the present study: Evaluation Using Cardiac Insertable Devices And TelephonE in Hypertrophic Cardiomyopathy (ELUCIDATE HCM).

OBJECTIVES
Primary objective is to assess the incidence of NSVT during 18 months follow-up using an ICM.

Secondary objective is to assesses the incidence of AF during 18 months follow-up using an ICM.

METHODS
Setting and selection
Adult patients with a confirmed diagnosis of HCM will be recruited from the catchment area of Region Gävleborg and Umeå University Hospital (tertiary centre) in northern Sweden. Eligible patients are identified from hospital databases (diagnostic codes I42.1 or I42.2) and validated using medical records. The recruitment started in August 2017. The device will be implanted in addition to standard care.

Inclusion and exclusion
Patients, aged 18–65 years, with a confirmed diagnosis of HCM are eligible for the study. Exclusion criteria as follows: aortic stenosis (moderate, severe), hypertrophy associated with metabolic disease (eg, Fabry-Andersen) and syndromes (eg, Noonan syndrome), systolic heart failure with ejection fraction ≤55%, pacemaker, implantable defibrillator, myocardial infarction, percutaneous coronary intervention, coronary bypass grafting, pulmonary vein isolation, Maze surgery, VT ablation, ectopic atrial tachycardia ablation, renal clearance ≤40mL/min (Cockcroft-Gault Equation), malignancy or other comorbidity with ≤5 years life expectancy, pregnancy (or planned ≤18 months), drug addition, severe psychiatric disease, not able to participate in 18 months follow-up, 5-year risk of sudden cardiac death ≥26% according to the risk calculator.19 Myectomy or alcohol septal ablation is not an exclusion criterion.

Implantation and monitor setup
The implantation procedure is performed in local infiltrative anaesthesia (carbocaine with epinephrine) using the standard operation kit for Confirm Rx via a 5 mm incision at the level of the fourth rib on the left side subcutaneously. The application for monitoring is installed on the patients’ own smartphone or a one that will be lent during the study period. The connection to the home-monitoring site Merlin is administrated and the patient is instructed how to use application and report potential symptoms according to guidelines.22 Postprocedure, paracetamol (acetaminophen) is recommended to control pain.

Programming
VT detection is programmed as 160 bpm during ≥8 intervals with high electrogram (EGM) priority and discriminator sudden onset activated (onset delta 18%) a bigemini qualifier off. An AF episode is recorded based on ≥2 minutes duration (the shortest programmable duration), AF-burden ≥6 hours a day or ventricular rate during AF 100 bpm for 6 hours daily. Bradycardia is recorded at ≤40 bpm or pause ≥30s. Patient-activated symptom episodes have high EGM priority with 6min symptom pretrigger duration and 1 min symptom post-trigger duration and the first 8 EGMs are stored. Maximal ventricular sensitivity is typically 0.15mV but adjusted if R-waves are low. Threshold start is 75% and sense refractory period 250ms and decay delay 60ms.

Follow-up
Patients are encouraged to report symptoms by using the smartphone application. In addition, every third month there is an automatic interrogation of the device and transfer to the home-monitoring site Merlin, which is reviewed every second day except for weekends. False detection of arrhythmia by the device is expected to be
frequent based on experience. Therefore, all episodes are scrutinised as part of work process. At 18 months, the device is explanted. Patients are scheduled for follow-up every third months but detection of arrhythmia warrants contact with the patient as part of clinical management.

Power analysis
A power analysis is based on previous research findings and estimation of outcome with certain relevance of hypothesis testing. This is the first study on incidence of NSVT and AF in HCM using continuous monitoring for a period of 18 months. Thus, the diagnostic yield is unknown. A formal power analysis have not been conducted and estimation of sample size is based on clinical judgement and available resources.

Statistics
Numerical data will be presented as frequencies, percentages, means and percentiles. Continuous variables are summarised as means, SD and percentiles and compared using t-tests. The χ² test is used for categorical variables. Kaplan-Meier estimates is used to describe time-to-event analysis (time from implant to AF and NSVT, respectively, and cumulative incidence at 6, 12 and 18 months will be reported).

A two-sided P value of <0.05 is considered statistically significant. The database will be stored in Excel 2010 and imported into SPSS V.22 (IBM) for statistical analyses.

Variables
Patient characteristics at enrolment as follows: age, family history of SCD, unexplained syncope, known HCM associated mutation, weight, length, NSVT at 48 hours ECG. Echocardiography parameters such as maximal wall thickness, left ventricular outflow tract gradient and left atrial size will be recorded.

Ethics and dissemination
This study is conducted in accordance with the Declaration of Helsinki. The study protocol, including variables and prespecified research questions, the study was registered at Clinical Trial Registration NCT03259113 and approved on 24 August 2017. Documentation of research data and management of study follow the Guideline for Good Clinical Practice. Each patient is informed about the study in both oral and written form by a physician and included after written consent. After the follow-up period is completed, the database will be closed and followed by statistical work, interpretation of results and dissemination to a scientific journal.

DISCUSSION
This is the first study on arrhythmia detection in HCM using an ICM. These devices offer the superior advantage of prolonged monitoring in comparison to external loop recorders. ICM is currently used in certain cases of HCM such as syncope evaluation or possibly in patients with frequent palpitations but not in routine evaluation.

The application of ICM in the specific group of HCM has been proposed already in statements of research priorities. The newly launched Confirm Rx uses a smartphone application that is used instead of a standard home monitor and provide the possibility of remote monitoring and symptom registration.

Until now, 48 hours ambulatory monitoring is used, but often telemetry in hospital wards detect arrhythmias in HCM. That means that these modes of monitoring may coincidentally detect AF and VT but with increased likelihood in patients with higher incidence of arrhythmias. It is unclear if a higher incidence of arrhythmia reflects a higher risk of SCD/stroke, and our study has a small sample size and no long-term follow-up of outcomes of SCD. Even though this study will elucidate the true arrhythmia incidence, the clinical interpretation will remain partly unsolved. In addition, ICMs are costly devices and health economy analyses will be needed before potential use in broader HCM groups.

Detection of AF is important in HCM because of the increased of embolic stroke. AF detection by ICM is superior compared with standard evaluation of monitoring in cryptogenic stroke. However, it should be remembered that clinical management of patients whose AF was detected at pacemaker interrogation is controversial, but there is compelling evidence when duration is at least 6 min. Patients with silent AF, that is, asymptomatic still carry a considerable risk and should be managed the conventional way with regard to anticoagulation.

Even though the definition of AF is an atrial electrical activity of ≥300 bpm during ≥30 s, devices such as pacemaker register atrial high rate and the benefit of apixaban is currently studied. The correlation to symptoms is possible in our study and future smartphone-based ICM usage is promising.

Safety aspects during the study imply referral to the patients’ physician for anticoagulation if AF is detected, sustained VT/ventricular fibrillation for decision-making with regard to an ICD and if a significant bradycardia occurs that implies a pacemaker indication. If an ICD or pacemaker is indicated, the ICM will remain until study ends at 18 months.

Future research of larger series of patients with HCM using ICMs with a larger sample size allowing for analysis of subgroups like patients who have undergone myectomy or alcohol septal ablation are welcomed. Interestingly, the ICM size has become reduced over time, and implantation techniques have become simpler, which allows for more favourable cost–benefit as implantation outside the electrophysiological laboratory is possible.

Still, this is the first study on arrhythmia burden and symptoms in consecutive unselected patients with HCM using an ICM connected to a smartphone for monitoring and symptom elucidation.
