Abstract
Autosomal recessive congenital ichthyosis (ARCI) is a group of monogenic skin disorders caused by mutations in any of at least 12 different genes, many of which are involved in the epidermal synthesis of ω-O-acylcereamides (acylCer). AcylCer are essential precursors of the corneocyte lipid envelope crosslinked by transglutaminase-1 (TGM-1), or a yet unidentified enzyme, for normal skin barrier formation. We hypothesized that inactivating TGM1 mutations will lead to a compensatory overexpression of the transcripts involved in skin barrier repair, including many other ARCI-causing genes. Using microarray, we examined the global mRNA expression profile in skin biopsies from five ARCI patients with TGM1 mutations and four healthy controls. There were a total of 599 significantly differentially expressed genes (adjusted P < 0.05), out of which 272 showed more than 1.5 log2fold-change (FC) up- or down-regulation. Functional classification of the latter group of transcripts showed enrichment of mRNA encoding proteins mainly associated with biological pathways involved in keratinocyte differentiation and immune response. Moreover, the expression of seven out of twelve ARCI-causing genes was significantly increased (FC = 0.98-2.05). Also, many of the genes involved in keratinocyte differentiation (cornified envelope formation) and immune response (antimicrobial peptides and proinflammatory cytokines) were upregulated. The results from the microarray analysis were also verified for selected genes at the mRNA level by qPCR and at the protein level by semi-quantitative immunofluorescence. The upregulation of these genes might reflect a compensatory induction of acylCer biosynthesis as a part of a global barrier repair response in the patient’s epidermis.

1 | INTRODUCTION

Autosomal recessive congenital ichthyosis (ARCI) is a heterogeneous group of rare monogenic skin disorders with a prevalence of 1:100 000. ARCI is characterized by a defective epidermal barrier reflected in an increased trans-epidermal water loss (TEWL) and a presumed compensatory hyperkeratosis. At birth, many of these patients present as collodion babies. Subsequently the skin phenotype...
transforms into either of four major clinical subtypes of ARCI, the most common of which is lamellar ichthyosis.\textsuperscript{[1–5]} Severe forms of ARCI often cause a reduced quality of life and usually require chronic treatment with systemic retinoids.

ARCI is caused by mutations in any of the following known genes: TGM1, ALOXE3, ALOX12B, ABCA12, CYP4F22, CERS3, NIPAL4, PNPLA1, SDR9C7, LIPN, SLC27A4 and SULT2B1.\textsuperscript{[1,5–7]} Additionally, mutations in ELOVL4, GBA, GJB2, CLDN1, SPINK5, STS, FLG, KRT1, KRT10 and KRT2 can cause similar ichthyosis phenotypes.\textsuperscript{[1,8–12]} Among the first group of genes, the majority are involved in the biosynthesis of ω-O-acylceramides (acylCer) and one encodes for an enzyme transglutaminase-1 (TGm-1) which cross-links cornified envelope (CE) proteins and might also be involved in forming the corneocyte lipid envelope (CLE).\textsuperscript{[1,13–15]} The gene products involved in acylCer biosynthesis are described in Supporting Information; the remaining genes referred to above produce various structural proteins and enzymes also essential for skin barrier homoeostasis.

Because TGm-1 is important in the final step of keratinization and many of the other mentioned gene products are preceding players in the formation of a skin barrier, a genetic deficiency of TGm-1 could hypothetically elicit compensatory gene regulations either via some pathway-specific feedback mechanisms or as a part of a more general epidermal repair mechanism.

To address this possibility, which has barely been studied in the past, we examined the global mRNA profile and expression of specific proteins in epidermis of patients with TGM1 mutations compared with healthy controls.

## 2 | MATERIALS AND METHODS

### 2.1 | Ethical statement

All studies were approved by the Regional Ethical Review Board (EPN) in Uppsala and conducted according to the Declaration of Helsinki Principles. Informed and written consent was obtained from the patients and healthy controls.

### 2.2 | Skin specimens

Skin punch biopsies were taken from the patients and controls (see Supporting Information) for RNA analysis and immunofluorescence staining as previously described.\textsuperscript{[16]}

A detailed description of the patients involved in this study can be found in Table 1 and in a previous report.\textsuperscript{[4]} In brief, all patients were males, aged 29–80; four of them were born as collodion babies and later in life required maintenance treatment with oral acitretin, which for ethical reasons could not be stopped to obtain naive skin biopsies for the study. Topical therapy consisted of emollients twice a day which the patients were asked to abandon on gluteal skin for 12 hours before sampling.

### 2.3 | Microarray analysis

GeneChip® ST Arrays (GeneChip® Clariom D Human Array) was used for the microarray analysis of gene expression (see details in Supporting Information). Data were analysed as previously described.\textsuperscript{[17]}

The array data are deposited in Gene Expression Omnibus of NCBI (accession number GSE107462).

### 2.4 | Analysis of mRNA expression using qPCR

cDNA was synthesized from total RNA as previously described.\textsuperscript{[18,19]} Semi-quantitative PCR was performed using TaqMan Gene Expression Assays (see Table S1 in Supporting Information) in an ABI7500Fast machine. Expression levels were measured in triplicate. The relative mRNA expression was determined by the $2^{-\Delta\Delta Ct}$ method using RPL19 as a reference gene.

### 2.5 | Immunofluorescence (IF)

Patient and normal human skin biopsies were frozen and sectioned at 6 μm in a cryostat. Tissue sections were fixed, blocked, immunostained followed by microphotography and image analysis as described in Supporting Information and Table S2.

Statistical methods are described in Supporting Information.

3 | RESULTS

3.1 | Transcriptome analysis in patients with TGM1 mutations versus healthy controls—initial results

We performed a microarray analysis to investigate the global mRNA expression profile in skin biopsies from five male patients (P1–5) with ARCI in different severity and various types of inactivating TGM1 mutations (Table 1) and four healthy controls (aged 39–68; C1, C2, C4 male and C3 female). Among the transcripts, there were 22,559 genes with UniGene ID, 599 of which were differentially expressed genes (DEGs) (Figure 1A and Table S3). The controls and patients were well separated by two principal components generated from the global expression data (Figure 1B). Out of these DEGs, 205 were increased >1.5 log2-fold-change (FC) and 67 decreased <−1.5 FC (which equals a 2.8-fold change after back-transformation), making a total of 272 markedly altered transcripts (Table S4) which were functionally enriched in different gene ontology (GO) terms (Figure 1C).

A number of DEGs were identified as ichthyosis-causing and lipid biosynthesis genes (Table S3). For instance, the expression of seven out of twelve ARCI genes was significantly increased, viz. SDR9C7, CYP4F22, ABCA12, LIPI, ALOX12B, SLC27A4 and CERS3 (0.98–2.05 FC), as was the expression of three genes causing other types of ichthyosis, viz. GJB2, GBA and ELOVL4 (1.66–5.69 FC). In contrast, CLDN1 showed decreased expression (~1.38 FC), and TGM1, NIPAL4, PNPLA1 and ALOX3 showed no significant differences compared to controls. Looking at the patients’ individual data (Figure 2), the patterns in P2, P3 and P5 with severe ichthyosis are strikingly similar, whereas P1 showed less pronounced changes consistent with a mild phenotype. The divergent expression pattern in P4 is however more difficult to explain (see Discussion).

With reference to lipid biosynthesis, two genes encoding key enzymes in the early steps of ceramide generation, SPTLC2 and SMPD1, were increased 1.59 and 1.09 FC, respectively (adjusted P < 0.054). Moreover, two fatty acid transporters, CD36 and FABP5, were markedly induced (4.12 and 3.84 FC). By contrast, CERS6, coding for an enzyme with preference for fatty acyl-CoA with carbon-lengths C14–C18,[20] was significantly reduced. Also, SLC27A2, encoding FATP2, a very-long-chain (VLC)-fatty acyl-CoA synthase that activates VLC fatty acids (C22–C24) to their CoA derivatives,[22] was significantly reduced.

3.2 | Gene ontology analysis

We used the Database for Annotation, Visualization and Integrated Discovery (DAVID) to examine clusters among the 272 DEGs with adjusted P < 0.05 for FC>1.5 or <−1.5 (Table S4). The results show additional clustering of DEGs coding for proteins associated with biological pathways associated with keratinocyte differentiation (GO:0030216) and immune response (GO:0006955) in Table S5.

**FIGURE 1** Global gene expression profiles. (A) Heatmap of gene expression profiles (22,559 genes with UniGene ID) of cDNA from skin biopsies of patients with autosomal recessive congenital ichthyosis (ARCI) carrying TGM1 mutations (P1–5; n = 5) compared to healthy controls (C1–4; n = 4) as determined by microarray analysis. The 599 genes that were significantly differentially expressed (adjusted P < 0.05) between patients and healthy controls are shown in the black box. Green colour represents relative lower expression and red higher expression. Data for controls and patients were hierarchically clustered together (one minus Pearson correlation distance metric) by MORPHEUS. (B) The data for controls and patients were also separated by principle component analysis (PCA). The principle components (PC) were generated by R program from the global gene expression data. (C) The 272 DEGs (above 1.5 FC and below −1.5 FC) were significantly enriched (Bonferroni adjusted P value <0.01) in different gene ontology (GO) terms by functional annotation clustering analysis with DAVID. Each GO term has a certain count number of enriched DEGs.

**FIGURE 2** Heatmap of ichthyosis-related gene expression profile. Heatmap of gene expression profiles of selected ichthyosis-causing genes in ARCI patients carrying TGM1 mutations (P1–5; n = 5) compared to healthy controls (C1–4; n = 4) as determined by microarray. Genes with significantly changed expression (adjusted P < 0.05) between patients and healthy controls are shown in the blue box.
Among the DEGs annotated to keratinocyte differentiation (also involving the formation of CE), eight small proline-rich proteins (SPRRs) were increased 3.18-9.31 FC (Table S6). Furthermore, involucrin (IVL) and two late cornified envelope proteins (LCE3E and LCE3D) were induced, as well as PPARD, a nuclear ligand-activated transcription factor known to promote keratinocyte differentiation and lipid metabolism in keratinocytes. In contrast, we did not observe any significant difference in the expression of the keratin genes.

Numerous DEGs were assigned to immune response and/or innate immune response (GO:0045087) in Table S5 and S7. Among the most strongly induced genes, four coded for calcium binding proteins; viz. S100A7 (psoriasin), S100A7A, S100A8 and S100A9 (8.70-11.29 FC). Also the antimicrobial peptide (AMP) genes DEFB4A, DEFB4B and PI3 (encoding SKALP/ELAFIN) were increased 4.16-9.99 FC. Furthermore, two serine (or cysteine) protease inhibitors, SERPINB3 (Clade B [Ovalbumin]) and SERPINB4, known to be affected in early inflammation and barrier dysfunction,[22] were among the most strongly induced (8.09 and 7.70 FC, respectively) (Table S3).

Two interleukin genes were significantly changed; IL36G (5.13 FC increase) and IL37 (~3.50 FC decrease), whereas other cytokine genes, for example, IL1, IL17 and IFNG, were unaffected. Lastly, three chemokines (CCL22, CCL2 and CCL20) with chemotactic activity for several types of inflammatory cells showed marked increases (2.16-11.64 FC).

### 3.3 Verification by qPCR

The array data, which indicated changes in the expression of many ichthyosis-causing and inflammatory-associated genes, prompted a re-investigation of the transcripts by qPCR for verification. In total agreement with the array results, mRNA levels of ABCA12, SLC27A4, ELOVL4, CYP4F22, CERS3, SDR9C7, ALOX12B and LIPN were all increased in patients versus controls, but not so for ALOX3, NIPAL4 and PNPLA1 (Figure 3A). In addition, five strongly induced transcripts, but unrelated to any known ARCI aetiology, viz. CCL20, S100A7, FABP5, CD36 and IL36G, were markedly increased by qPCR analysis (Figure 3B).

### 3.4 Verification by immunofluorescence staining

Some genes showing pertinent changes at the transcriptional level were also analysed at the protein level by immunofluorescence (IF) staining of skin sections (Figure 4A and B). By applying image analysis, protein expression—represented by median fluorescence intensity—was also analysed in different epidermal layers using recently developed pipelines for the CellProfiler software[23] (Figure 4C). It can be seen that the expression of CYP4F22, FATP4 (encoded by SLC27A4) and CerS3 in patient skin is markedly increased in the upper spinous and granular layers and also extends to additional epidermal layers compared to control skin (Figure 4A-C). S100-A7, which is almost undetectable in control skin, is highly expressed in the patients, especially in the differentiated layers of epidermis (Figure 4). Likewise, the fatty acid transporter CD36 was strikingly increased in the upper spinous layer and granular layer of patient skin (Figure 4), whereas fatty acid binding protein 5 (FABP5) was more variably increased in stratum corneum of some patients compared to controls (Figure 4), thus corroborating our microarray and qPCR results.

### 4 DISCUSSION

This study is one of the first addressing global changes in the cutaneous gene expression in ARCI patients with mutations in TGM1. The most pertinent findings are: (a) upregulation of genes involved in the formation of acylCer and CLE, all essential for skin barrier homeostasis and incriminated in the aetiology of what might be called lipodysgenic ichthyoses; (b) increased expression of various AMPs and cytokine genes involved in antimicrobial response and
4.1 Aberrational gene expressions related to lipid biosynthesis and CE/CLE formation

Lipid biosynthesis in epidermis occurs via several pathways essential for a proper barrier function. Our results, showing reduced mRNA expression of CERS6 and SLC27A2 involved in the biosynthesis of fatty acids and ceramides with shorter carbon chain length, probably indicate that the production of ultra-long-chain fatty acids (acylCer precursors) is prioritized in patients with TGM1 mutations. In line with this, the expression of SPTLC2 and SMPD1 and seven ichthyosis-causing genes involved in the pathway of acylCer and CLE formation was induced in the range of 2-4 times. Most of these abnormalities could be verified by qPCR analysis and IF staining of patient and control skin (see Figures 3 and 4).

The TGM-1 mediated incorporation of proteins into CE is a late, but crucial step in the formation of a skin barrier. Here, we report increased expression in TGM-1 deficient epidermis of many of the genes encoding CE precursor proteins, such as involucrin (IVL), several small proline-rich proteins (SPRR1A, SPRR1B, SPRR2A, SPRR2B, SPRR2D, SPRR2E, SPRR2F and SPRR2G) and late cornified envelope proteins (LCE3D and LCE3E), which might be considered a positive feedback response.

4.2 Effects on genes involved in innate immunity and inflammation

Induced AMP expression has been previously reported in ARCI patients with TGM1 mutations, as well as in TGM1-deficient mice.[24] Our study revealed a number of highly expressed transcripts encoding proteins with antimicrobial activity, viz. S100-A7, S100-A7A, the S100-A8/S100-A9 complex (calprotectin), SKALP/ELAFIN and beta defensin-4A and 4B. Several of the induced AMP genes may also alter keratinocyte differentiation and proliferation.[25] Our findings are reminiscent of the situation in lesional psoriatic skin,[25] except that the expression of Rnase7, LL-37 and dermcidin was not induced in the ARCI patients with TGM1 mutations. Typically, neither of these conditions is prone to skin infections despite the barrier abnormalities. However, other subtypes of ichthyoses, that is, harlequin ichthyosis caused by ABCA12 mutations, Netherton syndrome caused by SPINK5 mutations and epidermolytic ichthyosis caused by KRT1 or KRT10 mutations show increased prevalences of secondary skin infections, which can be attributed both to a more severe barrier failure and to distinctive abnormalities in the lamellar bodies secretory system that collectively decrease the bioavailability of AMPs.[26]

Speculatively, a stimulation of innate immune responses in patient skin might be a consequence of the observed reduction of IL37, which is a known suppressor of innate immunity.[27] Furthermore, an enhanced adaptive immunity, reflected in increased IL36G transcription in the array and qPCR analyses, may in turn induce various chemokines and psoriasin (S100-A7),[28–30] which was also observed in our study.

It is well established that the Th17/IL-23 pathway is induced in psoriasis[31] and a previous study of ARCI patients with TGM1 mutations could link this pathway to ichthyosis severity and inflammation.[32] Furthermore, an increased IL-17/IL-22 activation in peripheral blood in patients with lamellar ichthyosis was shown to correlate with clinical variables in a recent study.[33] Indeed, we could confirm increased expression of several of the previously reported
IL-17/TNFα-regulated genes, namely IL36G/IL1F9, PI3, CCL20, LCN2, DEFB4 and S100A9, whereas the expression of the cytokines IL17A, IL17C and TNFA was virtually unchanged.

### 4.3 | Effects on other genes related to keratinocyte differentiation

Earlier studies have revealed five genes essential for psoriasis development: PPARD, GATA3, TIMP3, WNTSA and PTTG1. In the present study, we also found an altered expression of PPARD, GATA3 and WNTSA. As a corollary, we note that a PPARγ/δ agonist has recently been shown to induce CERS3 and ELOVL4 in cultured keratinocytes.

### 4.4 | Proposed mechanisms for transcriptional changes associated with TGM1 mutations

The observed upregulation of a multitude of genes in the skin of patients with TGM1 mutations probably represents a compensatory mechanism for the severe barrier dysfunction elicited by a marked reduction or total lack of TGM1 activity. The eliciting factors involved in such a hypothesized compensatory mechanism are still unknown, but increased water flux in stratum corneum, abnormal signalling by epidermal lipids and a disrupted [Ca2+] gradient might all be involved. Actually, the latter proposal is supported by the marked induction of GJB2 observed in the ARCI patients. In the GJB2-deficient mice model for Keratitis-ichthyosis-deafness (KID) syndrome, an altered calcium distribution in epidermis results in abnormal lipid processing, thus implying GJB2 as an essential factor in barrier homeostasis. Further studies are required to clarify whether the changed expressions of many ARCI genes in patients with TGM1 mutations are unique for this type of ichthyosis or represents ingredients of a general barrier repair mechanism.

### 4.5 | Study limitations

Although this study involved only 5 patients (and 4 controls), the results were in many cases pronounced and principally the same patterns were observed in four of the patients. However, patient P4 (age 80, homozygous for a splice site mutation in TGM1 and acitretin-treated for 20 years) showed more equivocal results despite overt lamellar ichthyosis. Incidentally, all patients except P1 were dependent on systemic retinoid therapy that could not be interrupted for a minimum of 1 month required to obtain treatment-naive skin biopsies. Therefore, we cannot entirely rule out the possibility that some of the observed changes in ARCI-causing and other genes were affected by retinoids. In an indirect attempt to address this possibility, we exposed human epidermal equivalents (HEE) generated from wild-type keratinocytes to all-trans retinoic acid (atRA) in vitro (see Supporting Information) and found reduced expression of almost all ichthyosis-causing genes (see Figure S1). This response is similar to previous results in monolayer keratinocytes exposed to atRA and contradicts retinoid therapy as a cause of the abnormal gene expression changes in the patients. Primary keratinocytes from three of these patients with TGM1 mutations were isolated for functional studies, but the phenotypic characteristics were lost and problems in generating HEEs using these cells were encountered (see Supporting Information). Furthermore, we previously analysed several retinoid-regulated genes in healthy volunteers exposed to topical atRA and lamellar ichthyosis patients treated systemically with the retinoic acid-metabolism blocking agent, liarozole, and among all genes found to be upregulated in these reports, only CRABP2 was upregulated in the ARCI patients of this study. It is worth noting that in a previous study of CRABP protein levels in epidermis, increased expressions were observed in untreated patients with lamellar ichthyosis and psoriasis. Based on all these evidences, we conclude that acitretin therapy is an unlikely explanation to the transcriptional changes observed in patients P2-P5.

### 5 | CONCLUSION

The present study shows that disruptive mutations in TGM1 are associated with marked upregulations of several other ichthyosis-related and lipid biosynthesis genes, as well as modulations of gene expression important for CE formation and immune or inflammatory regulations, together probably constituting a repair mechanism for the epidermal barrier function.

### ACKNOWLEDGEMENTS

We acknowledge the work of the Array and Analysis Facility, Department of Medical Sciences at Uppsala Biomedical Center (BMC), Husargatan 3, 751 23 Uppsala. The study was supported by grants from Swedish Research Council (K2013-57X-22309-3), Uppsala University Hospital (AS19070 to M.V.) and HudFonden. We thank the patients and healthy volunteers for kindly participating in this study.

### CONFLICT OF INTEREST

The authors have no conflict of interest to declare.

### AUTHOR CONTRIBUTIONS

HZ, AV, MV and HT contributed to the conception and design of the study. HZ, ME, SW and MV performed the experiments. HZ, ME, AV and HT analysed and interpreted the data. The manuscript was written and reviewed by all authors. All authors read the manuscript and approved the submission.
