Sustainability in Scandinavia: Architectural Design and Planning
Edited by Ali Malkawi, Marius Nygaard, Anne Beim, and Erik Stenberg. 192 pp. with 200 illus., 233 x 284.5 mm, hard-cover, English
ISBN 978-3-86905-012-6
Euro 59.00, £ 49.90, US$ 68.00

The challenges of the global climate crisis are heightened in large part by a pervasive uncertainty regarding how architects and designers can address this challenge most effectively. In a situation where action is needed, but the correct strategies remain unknown, it is essential for architects to share their experiences and knowledge as broadly as possible. They must seek out perspectives that can help them overcome these impasses. When climate change was put at the top of the international environmental agenda more than a decade ago, Scandinavian countries were ready and able to respond quickly and methodically. Today, Scandinavia is still on the forefront of sustainable development, reorienting cultural engagement and economic growth to face climate change. The experience and knowledge accumulated by architects from Denmark, Norway and Sweden have the potential to enrich the exchange of ideas that is vital to a shift towards holistic thinking and sustainable architectural practice.

In this book, essential aspects of sustainability in architecture and planning are approached from many diverse perspectives. They exemplify the breadth and depth of explorations underway. The collection of writings is based on six years of visits made to the three Scandinavian countries, and sustained engagements with the schools of architecture in the capital cities of Copenhagen, Oslo and Stockholm. The book aims to illuminate lessons being learned by architects in Scandinavia, that are also relevant in a global perspective.

The main drivers of sustainability are highlighted through case studies that cover all scales from planning and infrastructure to buildings and components. The cases illustrate central themes such as energy, lifecycles, industrialization, durability, transformation, and history. More acutely architectural topics such as adaptability, integrated design, and architectural education/tradition further permeate the cases. At the same time, the projects exemplify the best practices of sustainable architecture in Scandinavia including housing, offices, cultural buildings, and urban development.

Ali Malkawi is professor of architectural technology at the Harvard Graduate School of Design and founding director of the Harvard Center for Green Buildings and Cities. Marius Nygaard is professor of architecture at the Oslo School of Architecture and Design (AHO). Anne Beim is professor of architecture at the Royal Danish Academy of Fine Arts Schools of Architecture, Design and Conservation in Copenhagen. Erik Stenberg is associate professor of architecture at the KTH School of Architecture and the Built Environment in Stockholm.
Scandinavian countries responded quickly and methodically when climate change became highlighted as the main international environmental agenda decades ago. Today, Scandinavia is on the forefront of sustainable development, with cultural involvement, economic growth, and climate change in mind. The experience and knowledge accumulated over the years by architects from Denmark, Norway and Sweden have the potential to enrich the international architectural community as it transitions its practice towards a more holistic and sustainability future.

In this book, essential aspects of sustainability in architecture and planning are approached from many diverse perspectives that exemplify the breadth and depth of explorations underway in Scandinavia today. The collection of writings is based on six years of visits made to these three Scandinavian countries, and sustained engagements with the schools of architecture in the capital cities. The presentation of these perspectives is intended to illuminate lessons being learned by architects in Scandinavia, and to share these ideas with a global audience.

The main drivers of sustainability are highlighted through case studies that cover all scales from planning and infrastructure to buildings and components. They treat global, regional, political, and cultural themes, and give each their specifically architectural significance. More acutely architectural topics such as adaptability, holistic thinking, and architectural education/tradition further permeate the cases. At the same time, the cases exemplify the best architectural practices of sustainability in Scandinavia.

Scandinavia is on the forefront of sustainable development, with cultural involvement, economic growth, and climate change in mind. The roots of this book began in a summer program conceived by Professor Ali Malkawi in 2010 while at the University of Pennsylvania School of Design. It is based upon many years of engagement with schools of architecture, leading practitioners, and stakeholders at the municipal level in the capital cities of Denmark, Norway, and Sweden.

The intention of that program was to educate students about the advancements that these Scandinavian countries have made in architectural design and sustainability, and to illustrate their specific commonalities and subtle differences. It was evident that little interaction has been established among the three nations in professional practice or academic approaches. The program was held in collaboration with partnering professors and their associated universities: Professor Marius Nyaard at the Oslo School of Architecture and Design (AHO) in Norway; Associate Professor Erik Stenberg at the Royal Institute of Technology (KTH) in Stockholm, Sweden; and Professor Anne Beim at the Royal Danish Academy of Fine Arts (KADK) School of Architecture in Copenhagen, Denmark.

In the fall of 2015, the symposium “Sustainability in Scandinavia” was held at the Harvard Center for Green Buildings and Cites at the Harvard University Graduate School of Design. A workshop with the main participants in the program followed, initiating the writing of this book. During two subsequent other meetings at KTH in Stockholm and AHO in Oslo, the contributors continued to work on the structure and content of the book and began to define its chapters.

This book discusses the essential aspects of sustainability in architecture and planning, with the intention to bring lessons learned in Scandinavia to the forefront. The main drivers of sustainability are highlighted through case studies that cover all scales, from planning and infrastructure to buildings and components. At the same time, the cases exemplify the best practices of sustainable architecture in Scandinavia, including housing, offices, and cultural buildings. Both historical and contemporary projects illustrate the strengths of their respective practices. They illustrate the diversity and enhancements of Scandinavian architecture and urban work.

The main themes of this book were developed on the basis of extensive dialogues between the authors. The discussions explored several dimensions of sustainability, including global, regional, political, and cultural topics that range in scale from the city to the building to a structural component. Global versus regional themes included climate, geographies, natural resources, and demography; political topics included economies, governmental, and societal structures; and, finally, cultural discussions included building culture, traditions and history, social culture, and aesthetics.

The commitment to sustainability in the built environment is prominent throughout Scandinavia. Although the three countries discussed here have much in common, their developments and differences in terms of sustainability are very much rooted in their varying geopolitical and cultural developments, natural resources, and climates.

In contrast to the US, and even Europe, Scandinavia developed a form of minimalism in combination with a strong concern for developing the “welfare state” after WWII. Scarcity of resources, extreme weather, and their respective sociopolitical movements impelled these nations to conserve and sustain resources. When climate change became highlighted as the main environmental international agenda more than a decade ago, these three countries self-imposed stricter emissions regulations. Among many other factors, their resource differences influenced and differentiated their building codes. For example, the use of biofuel and waste source energy is prominent in Sweden and Denmark, as opposed to Norway, which relies more on hydropower.

These three countries present sophisticated examples of infrastructure systems that allow energy to be exchanged, in some cases among buildings; in others, between buildings and transport systems. They also allow waste heat to be collected from incinerators, for example, and combined with other energy-generating systems. This provides planners and architects with the means to design systems and buildings that are integrative, durable, and highly efficient as regards energy exchange and balance.

Denmark

Denmark is a small country, with a total area of only 42,931 square kilometers. Natural energy sources and material resources have historically been limited and are still so today. Danish building culture has therefore grown out of material scarcity, necessity, and ingenuity—and today, these aspects form an architectural tradition of simplified, efficient, and creative design. These aspects are also at the root of how Danish architects are defining sustainable architecture today. A holistic idea of well-designed architecture that cares for its social and cultural context and composed of natural, sound materials is a core concern in most sustainable architectural solutions. However, this understanding has been seriously challenged ever since the energy crises of the 1970s, which led to a strong political focus on energy consumption and technologies for alternative energy resources in Denmark. Buildings began to be considered from the perspective of energy performance, and building legislation changed accordingly to address questions of engineering.

For decades Denmark has, among many efficiency-enhancing initiatives, prompted the use of district heating systems that reduce waste and improve efficiency. Denmark hosted the United Nations Framework Convention on Climate Change in 2009; in the same year, the city council adopted the Copenhagen Climate Plan, and formulated a vision for Copenhagen to become carbon-neutral by 2025. The first of these sets the ambition of reducing emissions by twenty percent by 2015. The second, the Copenhagen 2025 Climate Plan, is a holistic plan as well as a collection of specific goals and initiatives covering four areas: energy consumption, energy production, green mobility, and city administration.
Since the oil crises of the 1970s, Denmark’s policies have
striven for self-sufficiency in terms of energy supplies; initially, by
use of regional, and later by use of wind energy and waste incineration.
Today, Denmark is almost self-sufficient.

Pioneering architects are making exceptional strides toward reducing
the energy consumption of buildings, proposing design
strategies that make creative use of both new and reused
materials and components.1 The strictest, Building Class 2020, reduces
energy consumption by about fifty percent as compared to tra-
ditional building and materials and their environmental impact.

A sole focus on energy consumption in the building’s opera-
tion strategies that make creative use of both new and reused
materials and components from the perspectives of efficient
and pollution. Politicians, planners, and architects joined forces
in a great effort to recalibrate and renovate the existing building
stock. This has also provoked discussions not only about how architecture creates
value for society and individuals across economic, social, and
environmental perspectives, and working with less spoilage, how
cultural and aesthetic qualities are now, little by little, being taken into
consideration.

Sweden

Beginning in the early 20th century, the possibility of construct-
ing a new society through the built environment became ap-
development and its climate change goals have targeted local and
national aspects of economic and population growth, and
how that growth could be managed. Many municipalities have
eco-municipalities, which are suffering from overbuild-
and space preservation.

The seventeen goals of the UN’s 2030 Agenda for Sus-
tainable Development adopted in 2015 are now starting to
impact national and regional regulations for sustainable
building. A renewed interest in social sustainability (following years of in-
creased urban socio-economic segregation) is being coupled
with the environmental obsession. For instance, Stockholm’s ambition
to achieve the European climate-neutral 2040 target has been
translated into regulations for maximum energy usage in new construc-
tion. At the same time, the national building sector is search-
ning for new ways to reduce their environmental impact while
increasing production to meet demands for up to seven hun-
thousand new units of housing (and accompanying urban
infrastructure) by 2025.

Norway

Norway’s geographical location and dramatic topography cre-
to a mixture of climatic zones. The hilly and temperate
landscapes along the ocean coast and deep fjords are only a few hours by car from mountainous areas. The coastal
forested mountainous forest belt has supplied materials for diverse building
cultures adapted to the local climate. Inland farms were typi-
cally located in the most fertile areas, with low building densities and
the industrialized valley bottoms and below the chilly, windy hilltops. Local resources were uti-
ized for log construction and slates or turf cladding on roofs.

The political ambitions of near-zero energy and emissions zero in a life-cycle perspective.

The abundance of renewable hydroelectric power has enabled
domestic and industry, where further innovations in sustain-
able architecture and urbanism need to be developed and im-
plemented.

4. After ratifying the UN Paris agreement in 2016, the Nor-
wegian government proposed a climate act that binds future
sentiments in urban planning as well as a sustainable
architecture. The political ambitions of near-zero energy
and emissions zero in a life-cycle perspective.

The Planning and Building Act 6 regulates municipal au-
tority and public information and influence on planning
and building. This is vital to the social sustainability of urban
development, but has been weakened in the last decades by a
gradual transfer of property ownership and planning initiatives
in the private sector.
Think globally, act locally

This well-known and often-repeated truism couples responsible action within a closely circumscribed vicinity with wide-eyed awareness of broadly encompassing frameworks—those of the natural world, of course, but also those of history and culture. Architects who adopt this axiom are thus enjoined to develop projects that acknowledge conditions that are more extensively ambient than the building’s immediate site—regional and social topographies, understood spatially. On principle, this would seem to be a normal and attractive task, as nothing is more natural for architects than concern for spatial conditions. Among the arts, architecture’s special competency is the arrangement and construction of inhabitable spaces. Though this is a valid assumption, the focus here will be on another dimension of architecture (and architectural sustainability): the built work’s temporal dimensions. The basic premise is the uncontroversial definition: architecture gives durable dimension to the spaces of our lives.

While there is no agreement about who originated the truism cited above, it is frequently credited to Patrick Geddes, whose Cities in Evolution has inspired many generations of sustainability-minded architects and planners. An entirely credible alternative source is the philosopher René Dubos, who was one of the driving intellectual forces behind the Declaration of the United Nations Conference on the Human Environment of 1972, an international meeting that was held in Stockholm.

The city was a generous host, opening a number of its splendid buildings, among them the Royal Palace, to the attendees. Inside the residence, participants repeatedly reinforced the “think globally, act locally” principle when addressing matters of population, pollution, resource use, habitat preservation, and economic, educational, and urban development. Coincidentally, just before the conference, Sigurd Lewerentz had developed designs for expanding that very Palace, designs that demonstrated architecture’s contributions to a city’s spatial order very clearly. Lewerentz envisaged a new ensemble of public and private settings, proposing changes that would have creatively transformed, indeed improved, existing circumstances. Sadly, his project came to an end only months before the statesmen, scientists, and philosophers held their deliberations.

Thinking beyond a project’s boundary while acting within its proper limits was hardly new to Lewerentz in 1972. This approach can be seen very clearly in his well-known project for a cemetery in the same city, the Woodland Cemetery, designed in collaboration with Gunnar Asplund. That project’s contribution to our understanding of sustainable architecture, however, is not only as a spatial arrangement. Even more important—more challenging and decisive—is what the project teaches us about sustainability’s temporal dimensions.

Building Time

Given our typical concern for a building’s palpable concreteness, its readiness for direct and immediate use and experience, a work’s extended temporality will probably seem largely
insignificant, if considered at all. We tend to think that a con-
struction is as it should be when its materials, construction, 
layout and “look” exist in the way that was specified in design. Un-
finished and under-maintained buildings are unfit for life. In-
habitation begins when construction and reconstruction end.
Uncontroversial as these commonplaces may seem, they are contradicted by the equally plain fact that a building’s “move-in” and “photo-ready” condition never lasts very long, hardly more than a season, certainly not through the years and decades of its use, well after the builders have left the site.
“Houses rise and fall,” T. S. Elliot observed in Four Quartets, and they:

...crumble, are extended,
Are removed, destroyed, restored, or in their place
Is an open field, or a factory, or a by-pass.²

Succession, it would seem, is the result of environmental and cultural change. It is not, however, their governing principle, at least according to the poet. The poem’s solemn invocation suggests another sense of time, one that is nonlinear, not ex-
actly cyclical, but intelligible and familiar just the same:

Time present and time past
Are both perhaps present in time future,
And time future contained in time past.³

The basic question is, can we discover the same mingling of chronological phases in built works that present themselves as sustainable—an “interlarding” of past, present, and future? Considering the decades-long construction of the Stockholm Woodland Cemetery, as well as its extension beyond a few buildings into the wider landscape, one should ask whether the architectural—neither linear nor fully cyclical—life span of buildings and landscapes is not decisive in projects that seek to sustain themselves. The question can be refined more by considering what might be called the artificial and natural time of buildings, their schedules of construction, inhabitation, and renewal, as they unfold in concert with the passing of days, seasons, years, and ages.

Despite the appreciation of intelligent design and skilled craft, it seems there is no good reason to privilege a work’s first appearance over its later appearances. Our tendency to concentrate on the qualities of a building that display the designer’s intentions is a disciplinary prejudice that limits one’s grasp of likely change—the past understood as a former present and the future as a present yet to come—unless it is challenged, perhaps by the evidence that a building’s concrete reality, surely sustainability has a temporal register, along the indices of which its successes and failures can be measured.

The question becomes more specific: how might a design’s understanding of likely change—the past understood as a former present and the future as a present yet to come—be made legible on the surfaces or in the spaces of a built work? If architecture’s basic task is to convey knowledge of the ways that an individual exists in the world, how might an orien-
tation such as this be both spatial and temporal, topographical and historical?

Buildings live, and they die
Contemporary architectural theory, at both the center and mar-
gins of sustainability discussions, frequently returns to consid-
erations of life cycle. Duration/durability/endurance is the basic issue. Subtopics include recycling (materials), replacement (of elements), and life span (long- and short-term). The currency of these considerations should not lead one to assume they are recent discoveries. The understandings that excite designers and thinkers today were already topical in the 1970s, as we have seen in the principles of the Stockholm Conference, but they were no less relevant in the first decades of the 20th century, when the competition for the Woodland Cemetery was held, and well before that too.

Nor is it surprising that ideas of temporality in architecture, especially of deterioration and finality, entered into the design processes of the Woodland Cemetery, inasmuch as endings (also beginnings, thus cycles) could not be avoided. In fact, they had to be thematized, for the funeral settings and graveyards were dedicated to remembrance, which is to say keeping pres-
ent what had passed. Lewerentz observed that a single upright stone can make time’s passing vividly apparent. Duration will be plainly evident, he said, when upright elements stand against the forces that range across the earth’s horizons.⁴ This is be-
cause every work that is raised out of the ground suffers the effects of those forces, varying in direction, cycle, and intensity, through drought, seasonal, and annual changes.

The built work’s suffering begins on day one. The end of construction starts the clock of decay. Changes multiply as hours, days, and seasons pass: more marks on the surfaces, more erosion of carefully cut edges, and less regularity in de-
signed geometries. The overall tendency, of course, is down-
ward; eventually all the way down through 90 degrees. No build-
ing stands forever. Admittedly, it is a little premature to speak of ruins at the time of construction. Well-designed cemeteries can also, Lewerentz said, convey a “feeling of peace, emanat-

§
Context as Pretext
Before there was a project for the Woodland Cemetery, there was a given site, one with particular environmental conditions and cultural meanings. Speaking generally, it was a forest location—hardly something strange in Sweden. More particularly, it was a landscape in which groves of trees had been selectively cleared for the digging of quarries (gravel pits). The site was edged by farmlands on one side and a railway on the other. Those existing conditions, variously primitive and practical, suggested to Lewerentz and Asplund the development of a range of landscape elements: mounds, dells, valleys, knolls, paths, and enclosures. This is to say that anterior circumstances served as pretexts for the design’s narratives, in both their spatial and temporal configurations.

To treat context as pretext means not only taking it as an excuse for one element or another, but rather adopting it as a set of first premises or initial prompts—parts of a text, one can say, set out before the project begins. Many of the Cemetery’s paths, for example, were designed to follow the contours of the given terrain, edging its depressions where a meandering through-route was required, or turning against the slope when a realized ritual or exit was intended. Both cultivation and construction occurred in this way, working with and against existing conditions. And each approach had precedents. The forest had developed on the site over centuries, albeit for the purposes of gravel extraction and agricultural yield, thus construction of the site’s enclosures and contours was well underway before the architects arrived. The design of the Woodland Cemetery was thus not an instance of “fitting into the natural context,” because the context was as much an artifact as an outgrowth of environmental forces.

The Memorial Gardens laid out in the 1920 plan, much like the contour-defining paths, also took advantage of anterior conditions, by largely transforming, though not wholly eradicating them. In this case especially, what the architects found on the site was far from “natural.” The location for those gardens was one of the places where trees had been cleared and gravel pits cut. Although the old depression was retained in the design, the gardens did not precisely follow the existing conditions. And each approach had precedents. The forest had developed on the site over centuries, albeit for the purposes of gravel extraction and agricultural yield, thus construction of the site’s enclosures and contours was well underway before the architects arrived. The design of the Woodland Cemetery was thus not an instance of “fitting into the natural context,” because the context was as much an artifact as an outgrowth of environmental forces.

The requirements did not allow a large monumental building to emerge from nature. The building was therefore suppressed, and without any compromise, subordinates itself and merges with nature, the surrounding pines and spruces rising to twice its height.

No less inconspicuous, or perhaps even more so, is the low, earth-covered building nearby, among those in the Chapel’s precinct. This construction, a mortuary, was meant for temporarily housing caskets in cool temperatures before funeral services in the Chapel began. With a descending entry, dromos-like, earthed in on its other three sides, and covered with a turf roof, the building is as much a hollow in the soil as a work placed upon it. The “merge” is plainly evident, though no one mistakes the work for an outgrowth of nature.

Throughout the architecture of the Cemetery there are well-reasoned provisions that anticipate likely patterns of use. Knowledge of cultural patterns sustained this provisioning. One’s vivid, though easy, sense of architectural anticipations conveys a sense of the architects’ care and generosity. Consider, for example, a localized but rather inconspicuous treatment of the stone flooring: grieving mourners sitting on a wooden bench facing the casket of someone now gone will doubtless, as some point, find the image they face, and the loss it affirms, unbearable. The inevitable downward glance is greeted...
The quality of a project, independent of size or function, plays a crucial role in a bigger system of spaces, the health of our planet, and future lives. Every project should give something valuable back to the user and to society. Art can be an intrinsic part of architecture and an instrument to add quality. Daylight, equally, can be vital for the betterment of occupants’ health. Foremost, the architect can take an active, yet critical, stance toward rules to achieve better architecture and more sustainable solutions on material, economic, and social levels.

The Teachers’ House and D36 Green House are small infill projects in the city center of Oslo. Both have artwork integrated as part of the facade strategy and as part of the identity of the buildings, but with two different intentions: one facade symbolizes the importance of the work done by the users of the building, while the other reflects the importance of “blending into” the project’s location within a vulnerable green stretch.

The projects build on two fundamental approaches to sustainability, one solving the energy concept by deviating from the mainstream Norwegian practice, and the other exploring means of achieving social sustainability.

The Teachers’ House and D36 Green House have an important factor in common: daylight. In both cases, this architectural element works to ensure better health. Daylight is a key factor in the work of all architects; an architectural quality that is becoming extremely important as cities around the world are becoming denser and buildings are being built higher.

The two projects also exemplify how design strategies that question pre-accepted ways of thinking can imbue a project with future relevance. To do this, one must challenge rules and conventions and maneuver around them through dialogue and negotiation. Complaints are passive. These projects show how an architect can question contemporary practice by demonstrating new solutions in built examples. In this sense, each project participates in a discussion on a 1:1 scale on how to develop better design strategies.

The Teachers’ House (“Smykkeskrinet”) Category: Conference Center
Address: Osterhaus Gate 4, Oslo, Norway
Client: Union of Education Norway
Architect: Element Arkitekter AS
Artists: Jorunn Sannes (main facade) and May Bente Aronsen (acoustic art piece in lobby)
Engineers: Dr. Techn. Kristoffer Apeland AS, NEAS Norsk Brannconsult, Brekke og Strand Akustikk AS, Norconsult AS, Skandinaviska Glassystem AB
Entrepreneur: Tronrud Entreprenør AS
Floor space: 1,704 m²
Completed: August 2009

Art as an intrinsic part of architecture; the southwest facade of the Teacher’s House. Photo: Element Arkitekter AS.
The Union of Education is Norway’s largest union for teachers, with more than 150,000 members. To accommodate their need for a conference center, they purchased an empty plot and an existing apartment building from the late 1800s on a parallel street, adjacent to the existing headquarters of the union. The Teachers’ House project was awarded through an invitation-only competition in 2004. This project is an example of how architecture can work as a catalyst for improving the quality of a neighborhood and provide a new identity for a street.

Projects are often designated with a nickname that emphasizes the main concept of the architectural design. The Teachers’ House was called Smykkeskrinet (jewelry box), which refers both to the artwork on the main facade and to the large conference room, or box, which is the heart of the project. The artwork on the main facade symbolizes the importance of education and learning and embeds these cultural values and aspirations in the identity of the building. At the same time, the printed glass envelope serves as an instrument to reach the building’s energy goals.

The project began with an invitation to the chosen architect to join the project’s building committee, and take part in a total of 73 meetings with the client and the client’s advisor, learning, negotiating, discussing, and dealing with the ups and downs of the project. The committee entrusted the architects to appoint the engineers of their choice and the two most cutting-edge Norwegian artists to the team. The resulting close collaboration between the artist Jorunn Siannes and Skandina-viåka Glassystemer AB was very important to the development of the main street-facing facade. It is composed of two layers of glass with a mirroring art screen print on the outer surface of the inner glass. Due to the fact that the design of the Teachers’ House deviated radically from mainstream thinking, it took five years before it opened.

Philosophy of sustainability

The main strategy for the sustainability approach is architectural quality and long-term thinking. The durability of all the building materials chosen ensures that future operational and maintenance expenses will be minimized. This strategy is paired with a complementary focus on minimizing the use of materials. In part, this is also a reaction to the influence of the Norwegian insulation and mechanical ventilation industry. This influence has resulted in the excessive and unnecessary use of materials, raising huge environmental challenges and also leading to health problems, since airtight envelopes are frequently combined with the use of low-quality materials. Instead of three layers of highly insulated glass units, “poor” double glass was chosen for its capacity to allow the collection of free solar heat. Also, the weight of two layers of glass required less material to carry the loads. Slender concrete walls with moderate insulation were used instead of thick and highly insulated concrete walls.

The conference center is a “low energy house,” with an energy concept that opposed then-contemporary mainstream
Concrete staircase capturing sunlight through front facade. Photo: Element Arkitekter AS.
Section showing the energy exchange between sun, concrete floors and energy wells. Drawing: Element Arkitekter AS.
thinking and political guidelines, as well as many of today’s passive house energy strategies.

In Smykkesknæt, heat from the sun is collected in the thermal mass of the concrete structure. Both the southwestern and northeastern glass facades work as sun collectors, and the artwork on the main facade doubles as a sun screen to reduce overheating. The solar heat collected in the concrete is stored in ten energy wells reaching underground depths of between 150 and 200 meters. In the winter, heat pumps extract heat from the wells, and in the summer, the wells are used for cooling. The water that facilitates this heat transfer circulates through pipes integrated into the floor slabs and the main concrete staircase. Since glass walls and exposed concrete surfaces are key parts of the energy concept, acoustics became a matter of great concern. In the lobby, an art installation made of felt was designed by May Bente Aronsen. The seventeen-meter-long artwork solves the acoustic absorption challenge without reducing the area of exposed concrete. Another important acoustic strategy was to work with different sound zones. For instance, the main staircase has no acoustic absorbents, just exposed concrete. The reverberation is distinct, but once you enter the conference room, the sound is soft and well modulated. These acoustic transitions are important not just because of the spatial experience of contrasts in sound, but also because the use of acoustic material is reduced to a minimum.

Another important challenge for the project’s sustainability was to work around a law that states that the project must be connected to the district heating plant. This regulation does not distinguish between heat generated by fossil or renewable fuel. The solution was to connect to the district heating system, but just for peak periods (50–100 hours a year). Smykkesknæt exports excess energy to the existing buildings in the headquarters.

Key turning points
The first turning point in the project related to the core function of the Teachers’ House was the conference room. As the design developed and demand for programmed spaces evolved, the space available for the conference room became increasingly diminished. The client initially planned to sell the adjacent apartment building, which they owned and used temporarily for office space, once Smykkesknæt was finished. However, after this strategy was questioned, functional spaces for storage, the kitchen, toilets, and the main fire escape were integrated into the back house of the old building. This permitted the realization of the client’s original goal of making the conference room as large as possible. The second turning point was convincing the client that concrete should be the building’s primary material, which was critical to achieving the project’s energy goals. In the end, a design process that began with the client asking for slate (because concrete was considered “ugly”) concluded with the client insisting that nothing should be placed on the walls because the concrete work was so beautiful. This was a wonderful example of how sharing new knowledge with a client may lead to new perspectives and preferences. It was a great risk to propose exposed, in situ cast concrete, simply because Norway’s traditions with concrete are less developed than those in southern Europe. In the case of Smykkesknæt, the finished construction was able to transcend preconceptions. This was primarily due to one man on the contractor’s team dedicating his fullest enthusiasm, talent, and understanding of the material toward ensuring that the project would have beautiful concrete work.

Future relevance
Smykkesknæt is built for the future, allowing for the exchange of technical components as technology moves on. For example, a CO2 heat pump that only consumes one-sixth of the electricity used by the existing heat pump can be installed. The users state that the new building has enabled them to develop better courses and better lectures, and the key success factor mentioned is daylight. In a broader perspective, this can lead to better education and insights for teachers—and thus improved teaching and learning for the next generation.

In 2015, Smykkesknæt received the Houens Fonds Diplom from the Ministry of Culture, Norway’s foremost architectural prize. Through this distinction, it has become part of Norwegian architectural history and will remain a reference with future relevance.
Green House D36

Category: Housing; twenty-one apartments, ranging from 29 to 82 m²
Address: Dælenenggata 36, Oslo, Norway
Client: Infill AS
Architect: Element Arkitekter AS
Artist: Element Arkitekter AS/Hallvard Huse
Landscape Architect: Gullik Gulliksen Landskapsarkitekter AS
Engineers: Sweco AS, Fokus Rådgiving AS, AIL AS, GK AS
Entrepreneur: Eide-Entreprenør AS
Facade entrepreneur: Element Arkitekter AS, Uppe LTD, Modum Glassindustri AS
Floor space: 1,750 m²
Completed: October 2013

The project aimed to explore how a small plot could contain more dwellings and, at the same time, add architectural qualities to the surroundings. Building densely and close to transport hubs implies an environmentally efficient development that contributes to a better use of resources. The concept is based on a political strategy of urban repair and densification, which involves building housing on very small and complicat-ed plots of land—tiny voids or wastelands within the city. We initially cooperated with the client to identify 400 small plots inside the Ring 2 (ring road) around central Oslo. Each of these sites offers an infill opportunity whereby development might al-leviate the city’s desperate need for more housing.

D36 is located alongside a green path for pedestrians and bicyclists. The neighboring buildings are brick apartment blocks from the late 1800s in distinctive colors such as ochre, red, beige, blue, and green. The idea was “to give something back” to the city by respecting the lush green stretch. The house is a symbolic tree, a six-story artificial evergreen with a roof garden that allows for urban farming. A street-level shoe shop serves as a reception area and space for interaction with the neighborhood.

As in Smykkeskrinet, artwork is an integrated part of the concept. In this case, multiple layers of printed glass create effects similar to those of light filtering through a canopy of leaves. Conscious of the huge local intervention that a building in a park represents, this artwork aims to render the project both distinct and unobtrusive.

Planning the framework and regulations for D36 started back in 2003. The project’s approval was dependent upon several exemptions to codes and planning guidelines, and as a result, it took ten years before construction was finalized. Since the footprint of D36 is the same size as the plot, the pro-ject faced major challenges from the very beginning. According to Norwegian law, a percentage of the outdoor common space has to be provided on the ground. The garden was, therefore, moved to the roof, but with major resistance, as this did not comply with the regulations. Secondly, there are rules for a...
minimum amount of parking space within the project. This was solved through a contract that gave the residents access to rental parking spaces within 500 meters of their homes, and space for bikes was given priority within the project.

Philosophy of sustainability

D36 is highly sustainable in the sense that dense and compact living close to public transport nodes reduces area demand and greenhouse gas (GHG) emissions from cars. A general shift toward a sustainable building industry requires that the goals and aims of reducing emissions first have to be set by politicians. The building industry rarely aims higher than the minimum standards; this is how economy works. As in the Teachers’ House, durable materials were chosen to reduce operational and maintenance expenses. Examples include glass with ceramic print, solid wooden flooring, and thermally modified wood on the balconies. The climate in Norway is getting warmer, wetter, and more mercurial. Sudden heavy showers in cities are a big economic problem for society than seasonal flooding. The 50 centimeters of soil on the roof garden not only allows for urban farming, but also plays a crucial role in retaining rainwater and delaying it from pouring into the public stormwater system. Also, the social effect of gathering on the roof for both private and common events is highly valued by the residents.

Quality of living is not just a matter of the standard of a person’s apartment and how they interact with the neighbors, but also how the neighborhood works once that person steps out into the street. It is also about how the community works, where a person meets others, where she or he works, goes to school, or buys groceries. Architecture can serve as a health factor as well as a safety factor, and thereby contribute to social sustainability. The emphasis on economic sustainability is reflected in the choice of a rational 2.4-meter grid and a compact technical system organized in the core of the building. Considerable efforts were made to repeat building elements, optimize material, avoid wastage, and efficiently organize every inch of living space. For instance, an innovative window niche was designed that was capable of preventing the spread of fire, thereby enabling each floor to contain four apartments rather than three.

Key turning points

The first turning point arrived when, after an eight-and-a-half-year struggle, the authorities granted approval for the project to be constructed. The second turning point related to the supply of materials. The inner house was initially designed with a cross-laminated timber structure. But before construction could begin, the supplier shut down production. The primary structure was changed to concrete in order to allow construction to proceed, but the project was ultimately weakened in terms of conceptual integrity and sustainability, as the concrete structure was not integrated into the building’s energy/thermal strategy. Effectively, the potential thermal advantages of the concrete construction utilized in the Teachers’ House went unharvested.

The most critical turning point occurred when the final costs of another project by the same client were revealed. The numbers were alarmingly high, and D36 was put on a “budget diet” overnight. The project’s most conspicuous expense was the planned green planted facade, and so the client requested that an alternative be found, more specifically, a color with which to paint the facades. Three weeks were granted in which to find a collaborator willing to deliver the facade based on a revised budget. The strategy succeeded by teaming up with Uppe Ltd and Modum Glassindustri AS. In the end, the outer facade was mounted—on budget and on time—on a separate contract. To facilitate this change, a new facade system was designed. The new facade consisted of an inner skin of aluminum, which protected the wind barrier, followed by numerous layers of glass with artwork in ceramic prints.

The last turning point related to the project’s new fire-safe window design, an innovation that enabled one additional unit per floor. Due to the window niche’s unconventional design, the solution was turned down by the authorities just one week before opening day. However, when the fire engineers produced additional simulations for heat radiation during a fire, they were surprised to find that the design performed far better than the pre-accepted solution recommended by the authorities. This is a powerful reminder that innovation and non-traditional thinking are risky. Top expertise is needed to verify that a new design matches or surpasses the performance of conventional and pre-accepted solutions.

Future relevance

The concept of delivering the facade as a separate subcontract was used again in the next project. And, more widely, D36 has been an important catalyst in the debate on compact, quality living in Norway. The residents state that their daily life has improved since moving into D36, emphasizing daylight as the most important aspect. Research shows that daylight has a direct effect on health and well-being. In 1887, the Norwegian Sunhedsloven health law stated that the ceiling height in apartments should be a minimum of 2.4 meters. The same law is in effect today, but since that time, the average height of Norwegians has increased by approximately 20 centimeters. Therefore, Element Architects AS has set the goal of increasing minimum interior height to 2.7 meters. The idea of “2.7” was launched on Facebook and in the ROM Gallery in Oslo in the fall of 2015. This “health project” is truly idealistic; the work is not being paid for, but the problem is too important not to be pursued.
Embracing Complexity

___Tine Hegli

One of the dimensions of sustainability is to strive for public ownership of the built environment. The goal of responsibly managing common resources through social awareness and knowledge is key to success. The use of land and the appreciation for local culture and democratic values are also critical. Embedded in this mindset are strategies for a sustainable society. These strategies differ from project to project, and from site to site, but share a single motto: Be generous!

New large-scale structures occupy land, and, when they are constructed in dense city centers, the public will experience a loss of view and daylight or, if constructed on virgin land, a loss of ground that was already considered public. In all design processes, these matters are vital and are consciously analyzed to inform decision-making. Also, the knowledge of how to reduce energy use and related emissions of greenhouse gases to a minimum adds complexity to the decision-making process.

To balance concerns from these different levels—to evaluate, conclude, prioritize, and to see the big picture—are important exercises throughout design development. How can the design approach give value back to the local environment and enhance site-specific qualities? How can architecture stimulate new and unexpected experiences? Designs that manage this work as “testbeds” where new knowledge can be found. They hold iterative processes whereby architecture constantly can evolve and improve along with ambitions for the greater good of a society.

All parties that can enlighten the search for a successful built result should play a part in the design process. This includes representatives from the client and potential users across all relevant disciplines, stakeholders, artists, and people with knowledge of how to absorb, transform, and improve local conditions.

A collective design process results in a shared knowledge base and a shared investment in the “winning scheme.” This will, in turn, encourage all parties to take on the responsibility required to guard the ideas through later phases.

By gathering a broad mix of competencies, the process is less likely to be colored only by well-established roles and hierarchies. Narratives, diagrammatic concept sketches, analog work models, and intense dialogue are tools to communicate, translate, and merge ideas. Digital simulations, both to illustrate spatial potentials and performative achievements, are tools to make evaluations and iterations through which the design is optimized towards the goal. The two following projects focus on how ambitions concerning sustainability have influenced both teamwork and the architectural result.

Norwegian National Opera and Ballet

Category: Cultural building
Location: Bjørvika, Oslo
Client: Statsbygg
Architecture, Landscape and Interior: Snøhetta
Team of Artists: Jorunn Sannes, Peder Istad, Henrik Hellstenius, Axel Hellstenius, Inger Buresund
Team of Engineers: Erichsen & Horgen, Engineer Per Rasmussen, Reinertsen, Brekke & Strand Akustikk, Theater Projects Consultants/Rambøll Norge
Floor Space: Building: 38,500 m²; marble-covered public plaza, foyer, and roof: 25,000 m²

In 2000, when Statsbygg held an open international competition for the new National Opera and Ballet in Oslo, the area of Bjørvika was untouched. The site on the harbor front was cut off from the city center by heavy infrastructure and left as an industrial landfill. The plans for developing Bjørvika into a new attractive neighborhood with a mix of cultural institutions, service, and housing were on the table. The Opera was to be the catalyst in making this transformation possible.

Among 250 entries, Snøhetta won the competition with a scheme evolving from transformation, including the reinterpretation of the institution itself. The design approach included a democratic statement, where the central site was designed to accommodate the desires of both a rapidly growing city as well as the established cultural audience. Organizing the programmatic functions and volumes with the aim of keeping a low building silhouette, the design allowed for an accessible “roofscape” that could offer spectacular views for everyone visiting the site. This scheme seamlessly tied the Opera to future infrastructure and integrated the building into a continuous public space spanning from Jernbanetorget to the fjord, connecting the urban density of the city center to the unique qualities of open nature.

The public foyer space was presented as a continuation of this landscape, “the carpet,” where the visitors entered the building between layers of white stone, eliminating the threshold between interior and exterior. The balconies and main auditorium were wrapped in a wooden “wave wall” to enhance the same atmosphere, adding layers of associations to nature to the experience. The back-of-house functions, arranged around a courtyard to give daylight to the production areas, were labeled the “factory,” and designed for future flexibility. Large windows are main features of the rehearsal rooms and workshops of the “factory,” and designed for future flexibility. Large windows are main features of the rehearsal rooms and workshops that engage the Opera and Ballet machinery with the surrounding city.

Key elements in the design process

Awareness of daylight and its changing conditions in the Nordic climate played an important role in translating the nature narrative into the characteristic architecture of the Opera. Daylight is a nature-given resource crucial for human well-being at many levels. Yet daylight is also challenging to obtain as an interior quality because of heat loss and heat gain through glazed areas; the use of daylight requires additional energy for technical systems to balance heating and cooling. The efforts to resolve the Opera foyer, with its focus on light, exemplifies how design offers sustainable solutions with multiple dimensions. Developing the winning scheme from conceptual sketches into 1:1 construction details covering all functional and technical aspects of the sophisticated program required eight years of intense interdisciplinary collaboration. Several artists worked closely with the team of architects, landscape architects, and interior architects in defining strategies to materialize the narratives, and great attention was paid to keep these artistic intentions and qualities alive throughout all phases.

The size and scale of the marble landscape set the agenda for the “front of house” areas—the public spaces. In order to maintain the scale and atmosphere of this landscape, the absence of typical building elements was crucial. This ambition led the team to develop solutions where all technology required was integrated into the architectural design.

Natural light

Technical solutions, from the stormwater management on the marble roofscape to the integration of sprinkler systems in the foyer ceiling, were coordinated through the strategies described above. All strategies being equally important to the totality, the design process is best described through the daylight experience of the foyer.

To enhance the level of daylight and emphasize the notion of being in a semi-outdoor environment, the upper glass facade, the “lantern,” was solved as a structural glazing construction. Glass fins, with a depth of half a meter, were designed to tackle the wind loads, and to transfer the loads of the facade to itself to the superstructure hidden within the stone roof along the perimeter. Also, the glass quality was carefully studied to fulfill the vision of full transparency. The iron-free glass hardly changes the color of the transmitted light. During the day, the “lantern” appears to be made of crystal, like a prism playing with the light. At night, and even in the day during the dark seasons, the same facade qualities allow the warm colors of the wooden interior wall to be exposed to the city, indirectly lighting up the outdoor marble and transforming the house into a giant lamp.

Such tall glass facades are incredible sources of daylight, but at the same time they are challenging in terms of energy use for heating and cooling, as well as the discomfort of drafts. These hurdles were resolved by combining active technology, like radiators and fans, and passive design strategies based on the interaction of indoor airflows, architectural spaces, materials, and building parts.

The main heating system was based on thermal energy from district heating and distributed in the floors. Due to the large volume and thermal capacity of the stone, solar gain through the facade contributed positively to a comfortable indoor climate during the cold season. To avoid overheating in summer, there were several strategies in play that adapted to the architectural expression and programmatic requirements. The upper part of the main glass facade facing south has a patchwork of photovoltaic cells that serve as solar shading, still leaving fifty percent clear glass for views and light transmission. The monocrystalline cells have an efficiency rate of sixteen percent and produce 30,600 kWh of renewable energy (electricity) for building operations.

For the lantern, an inner solar screen was incorporated, reducing the total U-value of the glass facade. In the area where the central foyer floor connects to the Oslo fjord, the glass facade is recessed several meters to shade the south-facing café space as well as to protect the outdoor serving area from wind and rain.

The design of the wooden “wave wall” solves many of the air distribution strategies. Air inlets at the floor level are integrated in the pattern of the wooden slats together with acoustic panels. The wall openings are designed to provide city views from the balcony areas but, at the same time, keep the balcony separate from the foyer in terms of airflow. This displacement ventilation strategy allows the warm air to be retracted for heat recovery through the gap along the top of the wooden wall. In case of high temperatures, the air is released through hatches at the very top of the glass facades that also provide smoke ventilation. A seawater pump provides (free) cooling in the warm seasons.

To avoid cold drafts in the foyer during the winter season, fixed horizontal glass fins (one-third of a meter deep and mounted every three meters) direct cool air descending along the tall windows into the central volume, mixing it with the warm ascending air. For the coldest periods, radiators are positioned at the very bottom of the glass facade, built into the interior brim of the stone roof. This detail is also repeated at the ground floor.

The light marble floor is important for the lighting strategy of the public spaces, both during the day and at night. In the daytime, the polished surfaces reflect and spread light from the sky, from the fjord in the south, and from the open plaza on the north side. To avoid visible features of technology, the artificial lighting concept is based on the same sources, utilizing the light floor and ceiling surfaces as agents within an indirect lighting concept that includes lamps embedded into the architectural elements.

Resulting qualities
The design strategies of the Opera hold a mindset that is fundamental for a sustainable society: “Be generous!” The democratic values embedded in the public’s ownership of this grand structure gives it meaning beyond the cultural activities on show. The strategies that led to the architectural experience at the urban level also improved the performance of the building in terms of energy efficiency and environmental sustainability.

The Opera was included in the EU project “ECO-Culture” as one of three European energy-efficient cultural buildings that aimed at three main measures:

- Demand-controlled and energy-efficient ventilation systems, including control of relative humidity
- Daylight optimization, passive heating and cooling through facade design, lighting strategy and plumbing
- Integration of photovoltaic (solar cells) system on the south facade

Due to the diverse program and the specific functional requirements of the Opera, the solutions vary from one part of the opera house to another. The foyer and public areas serve as examples in this chapter.
Environmental design and sustainable transformation are key aspects of architectural value creation. The masterpiece of Danish modernism, Radiohuset, by Vilhelm Lauritzen Architects, displays a wealth of design strategies that are fully relevant to sustainable design today, and it offers two stories in one: the story of its original design, and the story of the building’s transformation into the Royal Danish Academy of Music.

Few buildings in Copenhagen seem more beloved than Radiohuset, the former headquarters of the Danish Radio Broadcast Corporation designed by architect Vilhelm Lauritzen from 1934–1945. Generations of broadcasters, audiences, musicians, concertgoers, journalists, pundits, and politicians have visited and worked in the building, which seems to inspire affection in people’s minds.

As a first-generation modern architect and a contemporary of Le Corbusier and Gropius, Lauritzen worked with the most advanced organizational principles and building technologies of his time when designing Radiohuset. Functionality was pursued with clear attention to technical performance, particularly acoustics, as broadcasting and musical performances constituted large parts of the building program. But Lauritzen was dissatisfied with the machine logic of the functionalism of his time. All scales of the building—from the articulation of a demanding urban site to the detailing of systems and surfaces—serve the purpose of creating a rich, vivid, and adaptable environment with human experience and interaction at its heart.

Modernist architecture has often been associated with problematic solutions, high maintenance, and expensive renovations. Radiohuset is, on the contrary, a case of sustained value creation based on original design principles established more than 80 years ago.

Fundamentally, value is an attribute rather than a property. It is socially constructed and reflects social exchanges and perceptions. In English, the word “value” can be synonymous to both “worth” and “quantity,” which offers a full range of applications from ethics to utility. Value, understood as worth, is about defining meaning, making sense, and putting to use. It underpins both social and economic exchanges and interactions. Karl Marx was first to theorize value creation in terms of the economy of industrial production (turning raw materials into commodities), commenting on the disruption of traditional (moral) values when all material and intellectual production was essentially marketable and tradeable: “All that is solid melts into air.”

Since Marx’s introduction of the concept Mehrwert, or surplus value, different concepts of value creation can be found. “Value added” is a term in economics depicting the value added by the production of a company, whereas in marketing, “added value” indicates the extra utility or attractiveness of a product or service that gives it competitive advantage on the market. Contemporary business theory combines these two dimensions into “value creation” as the core activity of an or-
ganization’s business model creating (or destroying) value by transforming natural, intellectual, human, etc., capital among different dimensions.4

When discussing sustainable value creation in the built environment through architectural design, we may apply the Brundtland Commission’s definition of social, environmental, and economic sustainability as base value dimensions. We can identify both cost and benefit sides to value creation. Regarding benefits, economic value relies on social interpretations of qualities found in the environment. Economic capacity enables work to produce beneficial outcomes, but there are always costs associated, not only in economic terms, but also in terms of social costs or environmental degradation. Sustainable value creation aims at maximizing benefits while ensuring that costs do not compromise resource availability for future generations.

Architecture spans many scales, from urban planning to construction detail, but also scales of time ranging from the relative permanence of sites and life cycles of cities, districts, and buildings to the ever-changing environmental conditions and everyday interaction of building occupants and users. Built environments are not finite objects. They require continuous work and adjustment and are susceptible to change as the activities they support evolve. As Brand noted, buildings are in a continuous state of transformation.5

The built environment has a metabolism of its own, differentiated through urban, building, and component scales. Buildings breathe and move with the flux of their occupants, with the seasonal changes in climate, and the daily variations of weather. Buildings change with time and adapt to the shifting purposes and preferences of identities and aesthetics. Sustainable architectural design creates value by enhancing environmental qualities across spatial and temporal scales that can accommodate changing social activities.6 Environmental design enhances the qualities of space for social purposes, while sustainable transformation is a discipline of working out design strategies that may both resist or accommodate change over the life cycle of a building.

The key to the lasting value of Radiohuset lies in the quality of the environment it creates aesthetically and functionally, both at the time of its construction and now, after being refurbished to serve the needs of the Royal Danish Academy of Music.

Radiohuset articulates a complex urban site and a demanding functional program that lasted 60 years with many interior changes. At the level of the detail, surfaces, furniture and claddings are designed for human sensation, comfort, and the experience of space, with a particular attention to light and sound that changes from moment to moment.

Functionality was a key concern in the commissioning. Chief Engineer Kay Christiansen was entrusted to set up a competent team for the assignment, choosing Christian Nøkkentved, a renowned structural engineer and acoustician, Ludvig Birch, a mechanical engineer; and Vilhelm Lauritzen, architect. The team was set to deliver a highly integrated design from the outset. Lauritzen was a colleague of Nøkkentved at the Royal Danish Academy of Fine Arts. He would fuse a scien-
tific approach to environmental performance and construction with a sensibility for the user experience of ambience, materiality, and spatial atmosphere.

Lauritzen and Nøkkentved relied on the newest developments in the then relatively new science of acoustics in order to develop design principles that allowed the acoustics of the building to be adapted for radio sound production and for concerts. A keen naturalist and a teacher of design and the rendering of color, light, and shape, Lauritzen would develop an approach marked by an interest in how building technology and natural forces might be shaped for the benefit of human habitats.

The acoustic protection of the sound studios from the noise of the adjacent road Rosenørns Allé was achieved by situating the studio block in the middle of the site, using the concert hall and the office blocks as sound barriers. On top of the studio block, a terraced roof garden landscaped by G.N. Brandt connects the buildings and offers fresh air and lush vegetation in this otherwise very urban setting. The composition of the solution is elegant, as it closes off the perimeter of the irregular urban block of which the building is part while maintaining clear identities and shapes of the buildings that constitute the ensemble.

Lauritzen uses the urban scale distribution to harness two fundamental values in the building: perfect acoustic conditions and a vibrant social space in the form of a canteen in the sunniest spot of the rooftop garden. Acoustic quality is pursued at all scales, from separated structural systems to differentiated absorption and diffusion. Acoustic quality is “stacked” by design choices at all scales. In the concert hall and the recording studios, the soundscape is shaped by wavelike geometries, diverse patterns of perforations, and the application of cladding materials, allowing the building users to interact with the building and to “tune” its acoustic response.

The environmental performance of the building was also highly adaptable with regards to lighting and ventilation. Daylight is abundant in the office wings, but it is also used throughout the building for orientation and wayfinding in the meandering circulation spaces. Electrical and ventilation service systems were state of the art, and Lauritzen’s office designed a range of original lighting fixtures for the building, some of which are still in production today.

Lauritzen celebrates environmental issues as an opportunity to design, as can be seen in the attention given to natural and artificial light as well as ventilation. Uplights designed for the reception area. Skylights, lamps and ventilation supply in the canteen. Photos: Jens Lindhe.
The stairs leading up to the concert hall balconies are generously lit from the sides. The softly curved profile is a recurring theme seen at all scales in Radiohuset, from the fan-shaped and dome-covered concert hall to the detailing of railings and wooden claddings in the interior. It is more than a formal gesture: The undulating surfaces, shapes and spaces serve a variety of purposes, from directing movement and inviting touch to regulating sound and minimizing structure. Photos: Jens Lindhe.

Indoor environment—acoustic challenges
The main challenge of the project was to design the education-
spaces in the office blocks. Yet at the same time, the process
provided some interesting knowledge about the relationship
between digital simulation modeling tools and the real life en-
vironmental experience of a group of expert users: world-class
musical educators.

The challenge was to provide excellent acoustics and a
high degree of control over ventilation, light, temperature, and
humidity in a listed building that faced a very trafficked road,
was poorly sound insulated, and had an obsolete service sys-
tem. The solution had to provide ample sound insulation be-
tween rooms and floors. The acoustics had to be perfectly dif-
fused with no flutter as well as being adaptable to varied use:
teachers and students should be able to change the reverber-
ation time from half a second to one second with minimal effort.

Quite a challenge, considering that half the facade area was a
continuous strip of poorly insulated windows with a very hard
acoustic response. The ceiling height of three and a quarter
meters was also less than perfect for the acoustics.

The design concept was to reintroduce a motif of undulating
panels found in Lauritzen’s original designs for the concert
hall and one of the studios. This effectively diffuses the deeper
tones. Panels with vertical ribs integrated at irregular angles in
the walls scatter the higher ends of the acoustic range and en-
sures sound diffusion across the entire audible spectrum. Cur-
tains can be drawn to reduce reverberation time, which can be
further reduced by absorbers behind openable panels in the
walls. A row of cupboards with oblique fronts scatters sound
at the end walls, and all floors, walls and ceilings were sound
insulated.

To test the design with the users, a full-scale educational
suite was built at the beginning of the construction process. The
design team had taken every precaution to analyze the acous-
tics. The user group, however, was quite unusual, consisting of
world-class musicians who work with their bodies and senses
as instruments. They are experts in indoor environments, albeit
in a more human sensation-driven way than a technical perfor-
ance-driven way. Accommodating their feedback, aided by
the acousticians, required modifications of the design, mainly
in the form of a checkerboard pattern of hard and soft surfaces
on the ceiling. It added sound diffusion and absorption hidden
behind a layer of acoustically transparent plaster. The expe-
rience revealed that there are finer aspects of environmental
performance—in acoustics, lighting, temperature, and humid-
ity—that even the most advanced digital modeling tools do not
simulate or predict adequately. Human sensation can register
differences that evade the models. As designers, we need to
train our sensitivities towards environmental qualities in order
to create better environmental results.

The design team found that Vilhelm Lauritzen’s original design
principles were so clear that it was possible to reinterpret
and reapply the architectural vocabulary of the original design
and achieve today’s technical performance. This very humble
approach to architectural interventions may not attract much at-
tention in the contemporary architectural press.

This process can be likened to the artist’s role in classical
music.1 The musician renders his or her interpretation of the
composer’s score as an original contribution and expression of
art. The art lies in an interpretation that invigorates the origi-
nal score and allows it to live on with continued relevance for
a contemporary audience. This is a notably different position
than that found in attention-seeking magazine architectures, but
it is a very rewarding one. A project can become a transfor-
mation by sharpening one’s attention and engaging in a con-
versation with past generations of architects.

The architectural philosophy of Vilhelm Lauritzen’s “func-
tionalism” transcends technical performance. The cultural sig-
nificance of the building and its care for the haptic experience
of users, as well as the ability to detail and the integration
of aesthetics and functionality teaches important lessons for
contemporary architecture.

Buildings subdue noise, create private, and delightful environments,
like Radiohuset, inspire affection. They are loveable and ap-
preciated by their users and public audiences alike. They are
the buildings that will be cared for, that will continue to find
new uses, and that will have the highest probability of having
extended lifetimes through successful transformations. Archi-
tectural quality is a way to create social values while managing
resources wisely.

The author wishes to thank Dryeers Fond and the Association
of Danish Architectural Firms for support in the publication of
this chapter.

1. The design team and client committee visited concert halls and
broadcast buildings across northern and central Europe as preparation.
“One knew most about how broadcast buildings shouldn’t be,” Lauritzen
said at the inauguration in 1945. The layout and shape of the concert hall
seemed to draw on the 1931 competition projects for the Palace of Soviets
by Le Corbusier and for a theater in Kharkov by Walter Gropius. See

Ali Malkawi is a Professor of Architectural Technology at the Harvard University Graduate School of Design and an international scholar and expert in building simulation, energy conservation, and sustainability in buildings. He is also the Founding Director of the Harvard Center for Green Buildings and Cities, a multidisciplinary research institution that seeks to transform the building industry through a commitment to a design-centric strategy that directly links research outcomes to the development of new processes, systems, and products. Malkawi has been engaged in many large-scale research initiatives and has published extensively. He has consulted on many high-profile projects and engaged with energy efficiency policies in several countries.

Anne Beim, M. Arch., PhD, Full Professor of Architecture at The Royal Danish Academy of Fine Arts School of Architecture. Head of CINARK - Centre for Industrialized Architecture that bridges the gap between the architectural education, the construction industry, and the architectural profession. Co-chair of the Graduate Program; Settlement, Ecology and Tectonics. Her research focuses on contemporary and historical theories/practices of building culture and tectonics, and addresses topics of ecology, architectural quality, building industry, materials, construction principles and detailing.

Erik Stenberg, Associate Professor in Architecture at the KTH School of Architecture and the Built Environment, Stockholm, Sweden. Assistant Director of KTH Center for a Sustainable Built Environment (www.chs.kth.se), Member of the Board of the Stockholm Chapter of Architects Sweden (Stockholms arkitektförening), and project leader of Grön BoStad Stockholm (www.gronbostadstockholm.se), a 3 year 62 MSEK EU structural funds project with the aim to make the housing sector in the greater Stockholm region smarter, greener and more socially sustainable. His research is focused on the history, practice, research, and politics of restructuring the large scale post-war modernist housing areas of the Million Program Era in Sweden.

Marius Nygaard is M.Arch. and Full Professor of Architecture at the Oslo School of Architecture and Design (AHO). He leads the school’s group for teaching and research in materials, structures and ecology. Nygaard has been leader of international research projects in sustainable housing and urban timber architecture. During 30 years as partner in architectural offices Nygaard led the design of complex urban developments, housing projects, and public and commercial buildings.
