Key points

Herbal medicine products and food supplements are increasingly used throughout the industrialized world.

* In this elderly population almost 30% were current users and women had a higher probability of being users than men.

* The probability of use decreased with increasing age, 28% were users in the age group 80-89 years compared to 14% in the age group ≥90 years.

* General practitioners need to consider the extensive use of herbal medicine products and food supplements among the elderly when making decisions about treatment.
Abstract

ObjecTive. To describe the users of herbal medicine products and food supplements with regard to age and gender specifically among persons aged ≥ 60 years. Design. A descriptive study with baseline data from a longitudinal study of the elderly, stratified into different age cohorts (60-69, 70-79, 80-89 and ≥ 90 years).

Setting. Blekinge county, situated in the southeastern Sweden. Subjects. In total 1380 persons aged 60-96 years (median age 78 years). Main outcome measures. Current use of herbal medicine products and the use of food supplements. Results. Of the participants, 264/1380 (19.1%) used at least one herbal medicine product, 184/1380 (13.3%) used at least one food supplement and 382/1380 (27.7%) used herbal medicine products and/or food supplements. In all regression models, women had a higher probability to use herbal medicine and/or food supplements in comparison with men. Focusing on the use of herbal medicine products alone and in the combination of using herbal medicine and/or food supplement, decreased use was seen with increasing age. However, 27.9% were still users of herbal medicine products and/or food supplements in the age group 80-89 years. In comparison, 14% were users in the age group ≥ 90 years. Age did not have an impact on the probability of taking food supplements.

Conclusion. General practitioners need to consider the high use of herbal medicine product and food supplements among elderly when making decisions about treatment.

Introduction

Herbal medicine products (HMPs) vitamins and minerals (food supplements) are widely used and increasingly prevalent throughout the industrialized world (1-7). Among US citizens a 380% increase in the use of HMPs and a 130% increase in the use of high-dose vitamin use were seen between 1990 to 1997 (6). Also in Sweden the prevalence of the use has steadily increased amongst adults during 1980s and 1990s; threefold for the use of HMPs and 70% for food supplements (8-10).

Among Swedish adults (16-84 years) the use is associated with age, gender, several sociodemographic-, and health behavioural factors (8-12). In comparison with men, females seems to be the more frequent users of food supplements, and among both men and women a high use is seen among the elderly population (9, 10, 12). In addition, the use of HMPs is higher among women compared with men and an increasing use with increasing age among men has been suggested (8-10, 12). The use is described in addition to traditional therapies and is related to high use of health care services (13, 14). It is reported to be used independently of conventional medicine and more than half of the users do not discuss their use with their physician (6, 8, 14). Consideration the potential toxicity of these drugs and to enable evidence based advice, health care professionals need to increase their knowledge of user populations. (5, 15, 16). Earlier Swedish studies have examined populations within a large age span and not specifically elderly persons (8-12). The aim of this study was to describe the users of HMPs and food supplements, with regard to age and gender, specifically among persons aged ≥ 60 years in a population based sample in a community in the southeastern part of Sweden.
Materials and methods

Study area

The study was performed within The Swedish National study on Aging and Care (SNAC), an interdisciplinary longitudinal study, which commenced in 2001 (17). This study includes baseline data collected between April 2001 and May 2003 from Karlskrona municipality (with 60600 inhabitants), situated in the southeastern part of Sweden. A random, age stratified sample was selected from the population registry among those aged 60, 66, 72, 78 and 81 years. Among those aged 84, 87, 90, 93 and 96 years the entire population was included. For easier management, the participants were divided into the following age groups; 60-69, 70-79, 80-89 and ≥ 90 years. The elderly received an invitation to participate in the study by post. New contacts, via telephone (three attempts), were made after 2 weeks to those not replying to the first invitation. The participants were invited to the research center and for those unable to come, a home visit was undertaken. Prior to the visit the participants were asked to bring a list or the packaging of prescribed drugs, non-prescribed drugs and used HMPs. To verify the use of current drugs, a research nurse interviewed the participants and filled in the questionnaire answers.

Definitions

In this study HMPs includes medicinal products in which the active ingredient or ingredients derive from natural sources, have not been processed too extensively and consist of part of a plant or animal, bacterial culture, mineral, salt or salt solution. Also, they are products suitable for self-medication in accordance with tested national tradition
or tradition in neighbouring countries with respect to drug usage (18, 19). According to the manufacturer’s description of intended use, HMPs were classified into the following indication groups: cardiovascular, psychiatry, gastrointestinal, musculoskeletal, urogenital and infectious (18). Food supplements includes vitamins and minerals normally found in, and consumed as part of the diet according to the established list from the European Parliament and the Council of the European Union (20). None of the used drugs were prescribed by a physician or other health care practitioners.

**Statistical analysis**

Descriptive statistics were computed to evaluate the data for sample characteristics. A Pearson chi-square test was used to test differences in the characteristics between groups and \( p < 0.05 \) was considered as statistically significant.

Binary logistic regression analysis was used to determine age and gender differences in the use of HMPs and/or food supplements. The statistical significance of the variables was determined using 95% confidence interval (CI).

The simultaneous relationship among the dependent variable and independent variables were modeled and evaluated by determining odds ratios (ORs). Possible interaction between the independent variables was tested. All analyses were performed using the statistical software package SPSS (Version 13.0).

**Ethics**

Ethical permission for the study was obtained from Lund University. Written consent was obtained from all participants.
Results

Characteristics of participants

A total of 2312 individuals were invited to participate in the study. In total, 1402 (61%) of those invited volunteered to participate.

Of the non-participants, 39% were men and 61% were women. Unwillingness involved 756/910 (83%), 92/910 (10%) considered themselves too sick and 62/910 (7%) were not possible to contact.

Of the participants, a total of 1380/1402 answered all the questions analysed in this study. The median age among the participants was 78 years (range 60-96) and the age distribution was: 392/1380 (28.4%), 340/1380 (24.6%), 524/1380 (38%) and 124/1380 (9%) respectively, in age groups: 60-69, 70-79, 80-89 and ≥ 90 years old. Of the participants, 576/1380 (41.7%) were males and 804/1380 (58.3%) females.

Use of HMPs and/or food supplement

In total, 264/1380 (19.1%) used at least one HMP, 184/1380 (13.3%) used at least one food supplement, 382/1380 (27.7%) used HMPs and/or food supplements. The distribution of gender and age among the users is given in table I. Among the users of HMPs and/or food supplement, 21/128 (16%) men and 45/254 (18%) women used more than one product simultaneously. Compared with men, women used more food supplements and also HMPs and/or food supplements (Table I).
Use of HMPs according to indication

Among the 264 users, 34 participants used more than one HMP. In total, 111/1380 (8.0%) used HMPs and were classified within the indication group psychiatric-, 74/1380 (5.4%) cardiovascular-, 38/1380 (2.7%) infectious-, 34/1380 (2.5%) musculoskeletal-, 23/1380 (1.7%) gastrointestinal-, and 18/1380 (1.3%) urogenital health related conditions. Women used more HMPs compared with men within the indication groups musculoskeletal- (Pearson Chi-Square, p= 0.011) and urogenital related conditions (Pearson Chi-Square, p=0.002). The distribution of used HMPs among the users according to indication group is shown in Figure I.

Logistic Regression Analysis

Dependent variables

Three different models were used, with the following dependent variables:
  - model 1) whether the participants took herbal medicine or not,
  - model 2) whether the participants took food supplements or not
  - model 3) whether the participant took HMPs and/or food supplements or not.

Each dependent variable was categorized on a binary scale (0 = no and 1 = yes).

Independent variables

No significant effect on the outcome was seen testing for interaction between gender and age group and was therefore not included in the model. Hence, independent variables were;

1. gender (0 = men and 1 = women),
2. age (stratified into the following groups: 60-69, 70-79, 80-89 and ≥ 90 years, coded as dummy variables).

*Gender and age as predictors for taking HMPs and food supplements*

In all analysed models the probability of taking HMPs and/or food supplements was significantly higher for women compared with men. In comparison with ages 60-69 years, significantly decreased use with increasing age group was seen in age 80-89 and ≥90 years among those using HMPs alone and in age ≥90 years among those using HMPs and/or food supplements.

Age did not have any impact on the probability of decreased use among those taking food supplements (Table II).
Discussion

We found that 1/3 of the elderly used HMPs and/or food supplements. Women had a higher probability of being users in comparison with men. Furthermore, the use decreased with age.

Most other studies have analysed populations’ historical use of these products (1, 2, 5-8, 14, 21). A strength in this study, minimizing risks for recall bias, is the analysis of the present use of HMPs and/or food supplements in a large population including the oldest people in Sweden. Even if the non-participants consisted mainly of women, this study included more women than men, giving only a small risk for bias due to gender differences among the participants. Since the questionnaire was confidentially treated and when necessary, close relatives helping those with difficulties in reporting their personal use, we find the risk for over- or underestimation to be negligible.

A shortcoming, also experienced by others, were the difficulties in comparing the use of HMPs and food supplements with other studies, due to different definitions of these preparations (22). When comparing our results with others, we have endeavoured to find and use definitions in agreement with the definitions used in this study.

Sex and age have earlier been shown to be most important factors for the use of HMPs (12). We did not find any significant differences in the use of solely HMPs between men and women. However, other studies from different regions in Swedish report elderly women as higher users of HMPs compared with men (8-10, 12).

As shown by others, also the women in this study used more HMPs and/or food supplements than men (almost 1/3 of the women versus 1/5 of the men (3, 8-10, 21).
The majority of the alternative medicine users reason that their usage is for prevention or treatment of existing illness (6). One explanation to the gender difference might be that women in general seem to be more observant of their health status. Several studies have found women to be more likely than men to carry out what they believe is health management (23-25).

More than 1/3 of those using HMPs in this study were classified in the indication group psychiatry related conditions. In addition, a study in Italy states that alternative medicines seem to have a complementary role for the elderly with self-perceived psychological symptomatology or depressive disorders (3). The second most common indication, cardiovascular conditions, involved more than a ¼ of the users. Urinary health related conditions concerned the smallest group of users.

We did not describe concurrent use of prescription medication. However, earlier reports state that elderly users with neuropsychiatry disorders are more highly represented in combining conventional drugs and herbal medicine products (3). In Eisenberg`s study nearly 1 of 5 of those taking any regularly prescribed medications, concurrently used at least one HMP, a high-dose vitamin or both (6).

The use of prescribed pharmaceuticals increases with increasing age but the opposite applies to the use of HMPs (11). The findings that the probability in taking HMPs alone or HMPs and/or food supplements decreased with increasing age are in accordance with a study from US were the users in the age group 60-69 years comprised 21.3%, in age group 70-84 years 15.3% and among those ≥85 years 9.1% (21). We have not found any other studies describing the use of HMPs and food supplements among the oldest population in Sweden (8-12). This fact pinpoints the importance of describing their use.
Despite limitations in drawing conclusions since they only represented 9% of the participants in this study.

We found a significantly decreased use in the age group ≥90 years. This might be due to the extreme aged impairment of daily life and/or are more dependent on those in their surroundings to purchase these products, economical limitations, an extended use of healthcare services and intake of conventional drugs and/or that the product marketing does not reach this population.

Although the use of HMPs decreased with increasing age, between 17.7%-30.1% of the participants in the age groups <90 years used at least one HMP and/or food supplements. The total number of users in our study is in alignment with a population-based study in the US where 18.8% of the adults mentioned their use of natural products (21). However there seem to be an even greater interest in using HMPs in the general population in the UK where 34% were users (7).

If the use goes unreported there is a risk of interaction when used together with conventional therapies and medicine (15, 16). By including this knowledge of the use of HMPs and food supplements on medical school curricula, physicians and health care practitioners would be better equipped to respond to patient enquiries about HMPs and food supplements and thereby fulfilling their role as patient advocates (26).

Studies aiming at epidemiological aspects of the use of HMPs and food supplements are few; they usually describe the use of complementary and alternative medicine in a wider perspective leading to difficulties in drawing conclusions of the use of HMPs and food supplements specifically (1, 2, 5-7, 14, 21, 27). As a complement to earlier Swedish studies, with a similar aim as in our study but mainly performed in other regions, this
study provides knowledge specifically focusing on an elderly population living in the southeastern part of Sweden (8-12).

In conclusion, almost 30% of the participants used HMPs and/or food supplements. The probability of being a user was greater among women than men. We found a decreased probability of using HMPs with increasing age. However, this did not apply to the use of food supplements. General practitioners need to consider the high use of HMPs and food supplements among the elderly when making decisions for treatment thus enabling evidence based advice.
Acknowledgement

We thank the Swedish Ministry of Health and Social Affairs, the Blekinge Institute for Research and Development and the County Council of Blekinge for funding this study. We are grateful to the staff and participants of SNAC-Blekinge for their help and interest in the study. We also thank Wendy Engman for reviewing the English manuscript, Anna Lengstedt for sharing her knowledge on herbal medicine products and Claes Jogreus for help with statistical analysis.
